When personalization deters delegation to algorithms: Evidence from a preregistered experiment

- Personalization deters delegation to algorithms rather than increasing it
- At first contact, delegation is lower for a preference-based than an EV algorithm
- Categorical non-delegation is far more common under personalization (16% vs 3%)
- Authority-based resistance: users trust the personal rule to match their preferences
- The EV algorithm loses more followers when `not delivering' after non-preferred picks
